

# Colorimetric and Resolution requirements of cameras

Alan Roberts

## **ADDENDUM 40 : Menu settings for Thomson/GV DMC1000 “Infinity” camcorder**

**This document is a report of the results of tests that are the precursor of those described in the EBU technical document Tech3335. It is not an endorsement of the product.**

A one-day assessment was made on a sample of the DMC1000, Infinity camcorder (serial number 1FRMR), a multi-standard HDTV cam-corder with a Canon HA17x7.6 HD lens. It is a novel camera in many respects, and is the first HD cam-corder made under the Grass Valley name by Thomson. Physically, it resembles many other camcorders, the familiar digibeta size and layout, but it has a large lcd side panel with touch-screen controls for menu control, and records to a Rev-Pro hard drive and/or Compact Flash cards. It has excellent connectivity, including a standard HDMI connector for the viewfinder, and USB client and host connectors for downloading content from the recording media. Remote control is possible through a PDA application. It also has many features which make it suitable for multi-camera use in studio or location shooting. Although production models may well differ slightly from this sample, a full manual was available. Much of the content of this document is taken directly from that manual since there was insufficient time to test many of the innovatory features.

Power consumption is 45 watts, a little high by modern standards, 49 watts when recording to RevPro. However, the power management and cooling system keep the camera cool to the touch, and acceptably quiet acoustically.

The camera has 3 full resolution (1920x1080) cmos sensors and is switchable between HDTV (at both 1080i/25 and 720p/50-line standards) and SDTV (625/50 and 525/59.94). It records to the selected medium in various forms: HD can be JPEG2000 (wavelets) 10-bit full resolution 4:2:2 at 100, 75 or 50Mb/s, or MPEG2 (i-frame only, 8-bit, 4:2:0 but full resolution) at 80 or 60Mb/s; SD can be DV25 (8-bit 4:2:0 for 625/50, 4:1:1 for 525.59.94), or JPEG2000 at 50, 50 or 30Mb/s, or MPEG2 at 50, 40 or 30Mb/s. MPEG2 compression requires an extra card to be fitted, it is not normally part of the camera. For these tests, there was not enough time to test all these formats, but previous tests, informal and unpublished, had already confirmed that the JPEG2000 compression did not limit the resolution or introduce any unwanted spatial aliasing.

The Rev-Pro recording drives are at present only 35MB each, but a larger 70MB version is promised “soon”. The Compact Flash sockets will accept Type I and Type II cards.

In this version, it was not possible to switch the camera to a film-look mode with progressive scanning at 25Hz, this is promised for a future revision of the camera. Also, it was not possible to examine the gamma curves in detail because the sawtooth test signal did not work as expected, therefore assessments were done using a Macbeth Colour Checker test chart. As a result, no recommendation can be made for a film-look setup yet. Also, the colour matrix selection is very strange, offering many matrices, none of which is calculated to optimise this camera. Nevertheless, colour performance was good although not exceptional, and when the gamma correction and knee were adjusted to capture about 2 stops of overexposure, the results were quite pleasing. However, noise levels were disturbingly high.

Noise performance was poor. Spatial aliases were visible in the 720 and SD pictures, but not to an excessive degree. Evidence for this is presented at the end of this document.

## **ADDENDUM 40 : Menu settings for Thomson/GV DMC1000 “Infinity” camcorder**

Many menu items have little or no effect on the image. Those that do so are highlighted, default values are bracketed where known. The full menus are given for completeness. Where two values are given {f} denotes film use, {v} video. The photographic speed of the camera is about one stop less than an equivalent SD camera, sensitivity is claimed as F/8 at 2000 lux, tests did not contradict this. Using conventional gamma and knee settings, about 2.5 stops of overexposure (about 600%) was achieved. Noise level is claimed as 54dB, and the total exposure range is estimated as about 11 stops. However, the camera noise performance does not appear to be that good, measurements were rather disappointing, details are given in the measurements section at the end of this document.

Simply switching the camera away from its native 1080-line mode inevitably introduces some spatial aliasing (a busy-ness in the picture). At 720 lines, there are aliases centred on 540 lines, indicating that the 720-line frames were being generated from the interlaced fields of the 1080 source. This is disappointing, since the CMOS sensors should, in theory, be capable of running at 1080p/50, a mode which is missing from the camera, but promised in a future upgrade. However, the SD down-conversions were acceptable, although the limiting SD resolution generated in any HD camcorder is always affected by the complexity (or lack of) of the down-conversion. Evidence for this is given in the final section of this document.

There are two sets of menus, slightly differing, one via the touch screen of the side panel, the other via the viewfinder. Many items are duplicated, I have not duplicated all the settings or comments in the section on the Viewfinder.

This document should not be used as a substitute for reading the manual.

## 1 Menus and settings, touch screen

### AUDIO MENU

#### Inputs

Audio levels

| Item        | Range                            | description                          | BBC |
|-------------|----------------------------------|--------------------------------------|-----|
| Front       | +30, +20, +1, 0, -10, -20, -30dB | Pre-gain level for Front 1 mic       |     |
| Rear 1 mic  | 0, +20, +40, +50dB               | Pre-gain level for Rear mic 1 input  |     |
| Rear 1 line | 0, +20, +30dB                    | Pre-gain level for Rear line 1 input |     |
| Rear 2 mic  | 0, +20, +40, +50dB               | Pre-gain level for Rear mic 2 input  |     |
| Rear 2 line | 0, +20, +30dB                    | Pre-gain level for Rear line 2 input |     |

#### Channels

Audio control

| <i>G&gt;R B&gt;R</i> |   |   |                   |
| G>R                  | 0~99 (50)   | Coefficient of G into R in variable matrix  |                   |
| B>R                  | 0~99 (50)   |   |                   |
| <i>R&gt;G B&gt;G</i> |   |   |                   |
| R>G                  | 0~99 (50)   |   |                   |
| B>G                  | 0~99 (50)   |   |                   |
| <i>R&gt;B G&gt;B</i> |   |   |                   |
| R>B                  | 0~99 (50)   |   |                   |
| G>B                  | 0~99 (50)   |   |                   |

<sup>1</sup> Setting Knee point to 50 should make it happen at 85%, but this could not be confirmed because the sawtooth test signal did not work properly and so the whole gamma correction process could not be fully investigated.

<sup>2</sup> There is only one filter wheel, with neutrals, colour temperature changes are done with gain changes, and so may well introduce coloured noise.

<sup>3</sup> Matrices are an issue. Although the colour performance with the "BBC" matrix seemed good, there has been no analysis or optimisation of a matrix for this camera, so all the matrices must be suspect. Hopefully, there will be a chance to derive a good matrix for the camera before it is widely distributed.

<sup>4</sup> Matrix-before-gamma is the colorimetrically correct thing to do, but placing the matrix after gamma-correction can be acceptable and can produce lower video noise.

| Shading       |                     |   |                  |
|---------------|---------------------|---|------------------|

## SETUP MENU

The basics

| Item           | Range  | description  | BBC      |
|----------------|--|--|----------|
| Formats        |  |  |          |
| Video standard | 1080i/50, 720p/50, 576i/50, 1080i/59, 720p/59, 480i/59 | Video standard. There is no progressive standard at 1080 <sup>10</sup> | 1080i/50 |

<sup>5</sup> Colour bars are SMPTE only in HD at 59.94Hz. Full height bars at 50Hz. This seems inordinately silly, because SMPTE bars are universally accepted as being "HDTV bars".

<sup>6</sup> In the camera under test, the sawtooth signal was clearly faulty, it did not start at zero/black level. This made it very difficult to assess the gamma curves, knee and black stretch options. Full settings for BBC use cannot be derived until this fault is rectified and the camera retested.

<sup>7</sup> Unusually, I can recommend using detail enhancement, because the camera's native performance is good and clean, and can withstand it, but this must be revisited when the sawtooth problem is resolved and the transfer characteristics properly assessed. The values given provide a good balance between horizontal and vertical detail, the Level value at 50 is about the maximum that should be used, and the noise slicer should be adjusted to prevent excessive magnification of noise at such levels.

<sup>8</sup> Level dependency usually controls the amplitude of detected detail below which it will not be enhanced. In this camera, the control, seems to have more to do with noise slicing than detail level.

<sup>9</sup> Because the knee could not be properly assessed, knee detail could not be assessed either.

|                               |  |  |         |
|-------------------------------|--|--|---------|
| Video source                  | CAM, SDI, CVBS                                       | Select what to record, so this is a vtr as well as a camcorder           | CAM     |
| Compress HD                   | JP2K50, JP2K75, JP2K100, MP2 60, MP2 80              | MPEG coding is requires an option card to be fitted                      | JP2K100 |
| Compress SD                   | DV25, JP2K30, JP2K40, JP2K50, MP2 30, MP2 40, MP2 50 |  |         |
| Media selection               | REV, CF1, CF2, Extern                                | Select the recording medium  |         |
| Chunk size                    | 10sec, 30sec, 60sec, 3GB, NoLimit                    | Sets the size of the recording blocks <sup>11</sup>                      |         |
| VF playback                   | Conf, Full   | Set VF for playback, Conf shows it "as is", Full is "maximised cropping" |         |
| Aspect ratio                  | 16:9, 4:3, LB  | Only for SD recording, LB places the 16:9 image in a 4:3 letterbox       |         |
| <i>Timecode</i> <sup>12</sup> |  |  |         |

| VF detail                     | On, Off  | VF sharpening  |         |
| VF detail lvl                 | 0~99 (50)  |  |         |
| <i>Lens</i>                   |  |  |         |
| <i>Auto iris</i>              |  |  |         |
| Auto iris                     | On, Off  |  |         |

<sup>10</sup> This is surprising, because the cmos sensors are themselves, progressive. The only possible conclusion is that the cmos sensors deliver interlaced 1080, and this has knock-on effects for the lower resolutions, see the measurements section at the end of this document.

<sup>11</sup> At first sight, there's no reason not to choose "NoLimit", but it might make more sense to use smaller chunks if there is any risk of the recording session spanning several storage devices.

<sup>12</sup> Timecode may well be redundant when this camera is used in a full tapeless workflow, since each clip is date/time stamped, and frames counted within the clip.

<sup>13</sup> In theory, DF TC should be relevant only when the frame rate is 29.97, this should not be selectable at 25fps

|                        |  |  |  |
|------------------------|--|--|--|
| Peak average           | 0~99 (65)  | Fade between peak and mean metering  |  |

| Gain B               | 0~99 (50)           |   |                  |
| <i>Exposure time</i> |                     |   |                  |
| Var. exp. time       | 50Hz~3270Hz (50)    | Variable shutter in 1/2Hz steps                   |                  |
| Lighting             | -10~10 (0)          | Shutter tweak to synch with 50/60Hz lights        |                  |
| <i>Color Temp</i>    |                     |   |                  |
| Temp M               |                     | Display only, colour temperature                  |                  |
| RE iris comp         | On, Off             | Exposure compensation for loss with lens extender |                  |
| <i>Detail</i>        |                     |   |                  |
| Detail               | On, Off             | All detail control                                | On <sup>15</sup> |
| Source               | Y, R, G, RG         |   | Y                |
| Level                | 0~99 (25 HD, 50 SD) | Overall level                                     | 50 {HD}, 46 {SD} |
| Vertical             | 0~99 (25 HD, 50 SD) | Vertical control, Level control also affects this | 13 {HD}, 24 {SD} |
| Noise slicer         | 0~99 (50)           | Noise level below which detail not affected       |                  |
| Coarse/fine          | 0~99 (50)           | Frequency of main correction                      | 50 {HD}, 33 {SD} |
| Soft detail          |                     |   |                  |

<sup>15</sup> Unusually, I can recommend using detail enhancement, because the camera's native performance is good and clean, and can withstand it, but this must be revisited when the sawtooth problem is resolved and the transfer characteristics properly assessed.

| <i>Matrix</i>            |   |  |      |
| Matrix                   | EBU, Skin, B/W, RAI, BBC, 1:1, CoolFL, Var1, Var2 | This area needs more development, to derive a correct matrix rather than a variety |      |

<sup>16</sup> There is no black-balance routine on this camera, it is all automatic, and seems to work well enough. There is an automatic routine scanning the picture continuously, mapping out any dead pixels.

<sup>17</sup> Knee could be fully tested in this measurement session because the sawtooth signal did not work properly.

### 3 Measurement results

#### 3.1 Colour performance

Assessments were made visually, using Macbeth charts as usual.

#### 3.2 Resolution

A HDTV zone plate chart was used (Figure 1, the illustrated version being for 480-line video). This contains six circular patterns that fully explore the spatial frequency performance of the camera, up to 1920x1080 pixels per width and height. Three patterns are grey-scale for testing luma performance, three more are coloured for examining chroma resolution or other colour filtering. Modulation is cosine rather than square wave. Each pattern is a “phase space” map of the possible frequencies that the camera can be expected to deal with, reaching 1920 pixels/picture width (960 cycles) horizontally, and 1080 lines/picture height (540 cycles) vertically.

Figure 1, zone plate test chart

##### 3.2.1 Resolution 1080i-line HDTV

Figure 2 shows a single quadrant of one grey-scale pattern; for this exposure, the camera detail enhancement was turned off, so this is the native performance of the camera. There are no visible alias patterns, apart from a feint one centred on 1080 lines (top of the pattern). This confirms that the sensors are 1920x1080. Also, the clean horizontal resolution indicates that there is probably no “precision offset” of the green from red and blue sensors, a common technique to enhance resolution in cameras. The clean way in which the amplitude of the sine-wave patterns falls to the limits confirms that the resolution has been limited with an optical “quarter wave” plate or similar technique. This is very encouraging

However, it is clear that the horizontal resolution is better than the vertical, not unusual in an interlaced camera, but it hints that the interlacing process is happening very early in the camera.

There were no alias patterns resulting from frequencies beyond the limits of 1920x1080 video.

Figure 2, HD 1080-line, no detail

### 3.2.2 Detail enhancement at 1080i HDTV

For a film look (not possible in this camera at 1080-line because it does not, at present, support the normal psf format at 1080i), detail can simply be switched off, and the results will be a good match to super 16 film. However, for a 35mm look, a little enhancement would be a good idea. Clearly, this must be retested when the sawtooth test signal problem is solved and the camera supports progressive scanning at 25Hz (psf).

Since the native resolution is very clean, it is possible to use rather more detail enhancement than usual. Some initial experiments resulted in a set of control values that resulted in a reasonably well balanced performance, both horizontal and vertical. The results for the same quadrant of the chart are shown in Figure 3. Clearly, the outer edge of the chart is a little too sharpened, but the enhancement has not revealed any aliasing and in theory at least could be used for a “video look”. However, such extreme enhancement should be used with care, since it has emphasised the noise somewhat, and so the noise slicer control should be adjusted to prevent that happening. The values used are:

- Level            70
- Source          Y
- Coarse/fine    50
- Vertical        13
- Soft            On
- Soft level     30

The overall Level setting is a collective control of the detail enhancements; the high setting (default is 50) caused excessive interlace twitter on a high grade HD crt display until the Vertical control was reduced below the default setting (25). Since this was an exercise to explore the camera, noise slicing was not investigated in detail.

Figure 4 shows the result for the same mixture of settings, but with the overall control (Level) lowered to 50. The annoying dark edge to the pattern has largely gone, and noise is less of a problem, but would probably improve if the noise slicer level were raised a little. The faint vertical alias pattern shows the level of interlace twitter seen on the crt display, on a large flat-screen display (1920x1080 resolution with the internal scaler disabled), this alias was not visible at all.

Figure 3, HD 1080-line, maximum detail

Figure 4, HD 1080-line, detail Level=50

This performance would be perfectly suitable for normal video performance, a “television” look, subject to setting the noise slicer. Note that this setting might have to be changed for various settings of the camera gain control. In the short time available for these tests, it was not possible to explore this further.

### 3.2.3 Resolution 720p HDTV

Figure 5 shows the camera performance at 1280x720, with detail switched off. This is less encouraging than the performance at 180-line.

There is a horizontal null zone (plain grey) centred at 1280 pixels, and aliasing plainly visible above that albeit at levels that are probably low enough to be acceptable. This aliasing would appear as a general “busy”-ness in pictures with fine detail (hair, waving grass, undulating water), but could probably be reduced or even eliminated by fitting a light diffusing filter to the lens. It results from the lens delivering, to the sensor, frequency content above the 1280x720 limits of this format, while the in-built optical spatial filter is properly tailored to the inherent 1920x1080 resolution.

Vertically, there is a bigger problem. The null zone is at 540, not 720 as expected. This, and the strong aliasing at higher frequencies, provide evidence that the scaling from 1080 to 720 (the forming of 720-line frames) is being done from the 540-line interlaced fields, and not from the progressive resolution of the sensors themselves. This is disappointing, but may well go away when the promised upgrade to 1080psf/25 appears, since it requires that the sensors are read progressively, and not with interlace.

Nevertheless, the effects of detail enhancement were investigated.

### 3.2.4 Detail enhancement 720p HDTV

Figure 6 shows the results for the detail enhancement with the same picture as for 1080-line, Level=50. Although the dark ring surrounding the pattern is reduced, the principle effect is to enhance the aliasing in a rather unpleasant manner. It also reveals some aliasing at 720-line, as well as that at 540.

Figure 5, HD720, no detail

Figure 6, HD 720, detail Level=50

Clearly, the detail settings for 1080-line do not work well at 720-line, and cannot really be expected to work well since the presence of aliasing is rather disturbing.

### 3.2.5 Resolution SDTV

Figure 7 shows the 576i-line down-converted picture with detail enhancement off.

Horizontally, the aliased and wanted frequencies are of equal amplitude at about 640 pixels, but the aliases spread out to about 1000 pixels but there is no disturbance above that value. Vertically, there is little wanted frequency content above about 320 lines and aliases are visible, albeit only faintly, between 720 and 1040 lines. Moreover, there is a steep decline in the frequency response between 175 and 320.

The pictures were subjectively soft and the presence of the aliased components shows that the down-sampling filters could be done better.

The performance at 480i appeared to identical, suggesting that the same filtering is used for both formats.

Figure 8 shows the effect of maximal detail enhancement, with the following settings:

- Level 99
- Source Y
- Coarse/fine 33
- Vertical 24
- Soft On
- Soft level 30

The vertical detail settings was as high as could be tolerated before objectionable edge effects occurred.

Horizontal aliases extend to 995 pixels, vertical aliases are more visible in the range between 540 and 1080. The wanted vertical resolution is now visible up to about 440 lines, and the droop in vertical response is almost corrected. However, this level of enhancement does not look nice at all, dark edges are clearly visible on the pattern boundary.

Figure 9 shows the result for the best compromise setting found during the tests, Level=46. The aliases are at lower amplitudes and the overall effect is less distracting. However, the pictures were significantly less sharp and alias-free than should be demanded in a camera making SD pictures for broadcasting purposes.

Figure 7, SD 576i, detail off

Figure 8, SD 576i, detail maximum

Figure 10 shows the effect of the same settings at 480i-line. There is very little difference between the 480 and 576 performance in the wanted detail. However, the vertical aliases are rather more visible, and there is a partial null zone (grey with little detail), centred on about 216 lines.

### 3.3 Noise performance

Measurements were made by exposing the camera to a plain white card, evenly lit, highly defocused. The camera gain was set to 0dB and exposure was set to generate video signals at 4 levels over the signal range. Data files were saved either to a data store via HDSDI or directly in the camera to SD card. Software analysis was then used to convert the files to BMP format, and to measure the rms noise levels in each file, using specialised software. The detail enhancement Level was set to 70, to see the worst scenario.

The noise level at about 50% is representative of the camera performance with gamma-correction switched off, because the ITU.709 curve has a slope of unity at an input level of about 28%, which corresponds to an output level of about 52%.

Figure 9, SD 576i, detail=46

Figure 10, SD 480i, detail=46

#### 3.3.1 Noise at 1080i HDTV

The distribution of noise levels over the grey scale conforms well with the slope of the gamma correction curve, and is perfectly normal. However, the numbers do not make good reading.

The camera manual contains a specification figure for noise of 54dB in HDTV mode. That figure is not reached in any of these measurements.

It is clear that operating at 720-lines gives a noise advantage of about 4.5dB, this is to be expected because the down-conversion algorithm involves the weighted averaging of neighbouring pixels, which reduces noise. Also, it is clear that this maximal detail enhancement is adversely affecting the noise by a dB or so, judicious adjustment of the noise slicer should cure that.

There is one bright prospect though; since the gain control allows setting to -6dB, the noise performance can be improved by 6dB with the loss of one stop of overexposure headroom. Unfortunately, since the sawtooth test signal was not working properly for these tests, it was not possible to measure the headroom reliably, but the informal tests done using a Macbeth chart showed that headroom could be about 2.5 stops (600%), therefore loss of one stop may not be an issue.

**3.3.2 Noise at 576i SDTV**

Noise levels should be about 6dB better than for HDTV since there is an element of pixel-averaging involved in the down-conversion process. Measurements were again made at 0dB gain, but with the “optimal” detail settings found for SD working.

| Level | Noise  |
|-------|--------|
| 10.2% | 39.1dB |
| 23.7% | 43.2dB |
| 51.8% | 48.2dB |
| 88.5% | 51.3dB |

Even at SDTV, the noise near 50% video level is 6dB worse than the specification for HDTV. This is disappointing.

| Std   | Gain | Detail | Level | Noise |
|-------|------|--------|-------|-------|
| 1080  | 0dB  | off    | 8.0%  | 33dB  |
|       |      |        | 22.1% | 37dB  |
|       |      |        | 46.3% | 39dB  |
|       | +6dB | on     | 84.1% | 40dB  |
|       |      |        | 44.9% | 38dB  |
|       |      |        | 44.9% | 31dB  |
| 720   | 0dB  | on     | 46.6% | 26dB  |
|       |      |        | 9.6%  | 36dB  |
|       |      |        | 23%   | 39dB  |
|       | +6dB | on     | 45%   | 41dB  |
|       |      |        | 83%   | 42dB  |
|       |      |        | 43.7% | 35dB  |
| +12dB | on   | 46.2%  | 28dB  |       |

**3.4 Conclusion**

Resolution at HDTV 1080 is good. There are significant and visible aliases in the pictures at both 720p and SDTV resolutions, the levels may be acceptable in practice.

Noise performance is poor, the camera does not meet its specification.

Colour performance was acceptable, but could probably be improved by installing a colour matrix calculated for the camera, and eliminating all the preset matrices.

The gamma-correction could not be fully investigated because of a fault in the internal saw-tooth test signal.

The camera should be retested when significant improvements have been made.

# Thomson/GV DMC1000 Infinity

## Second tests at Kingswood Warren, April 4 2008

### 1. Noise levels at 0dB gain.

| File | Video level | Noise level |
|------|-------------|-------------|
| 2    | 0.930       | -42.24dB    |
| 3    | 0.464       | -45.57dB    |
| 4    | 0.237       | -45.97dB    |
| 5    | 0.086       | -43.06dB    |

Noise performance usually follows the slope of the gamma curve, since noise is generated mostly in the analogue front end of the camera. Although the gamma curve selected in the camera was called “CCIR” it is probably intended to be that of ITU.R-BT 709 (left-hand plot).

Thus the noise levels for these four measurement points should be expected to follow the log of the slope, so at 93%, the noise should be about 5.8dB lower than at 27.8%, where the slope of the gamma curve is unity. Also, at 8.6% the noise should be about 5.5dB higher. However, the measurements vary only by about 3.5dB instead of 11dB, implying that some noise is being generated after the gamma corrector. This is unusual, and rather surprising.

The “safety check” is to measure the noise at high gain, to discriminate between front-end and processing noises.

### 2. Noise levels at 12dB gain

| File | Video level | Noise at +12dB | Equivalent noise at 0dB |
|------|-------------|----------------|-------------------------|
| 6    | 0.900       | 36.86dB        | 48.86dB                 |
| 7    | 0.461       | 38.50dB        | 50.50dB                 |
| 8    | 0.246       | 36.83dB        | 48.83dB                 |
| 9    | 0.117       | 33.45dB        | 45.45dB                 |

Noise at +12dB is considerable, and the distribution is a little greater than at 0dB gain. The right-hand column removes the effect of the 12dB gain and predicts the noise at 0dB; the values are significantly different from those measured at 0dB, and this confirms that noise is being added after gamma-corrections.

The camera’s noise specification is for -54dB, it misses that figure by at least 8.5dB at 0dB gain.

### 3. Noise levels in linear mode

One measurement was taken with gamma-correction switched off and 12dB gain.

| File | Video level | Noise at +12dB | Noise at 0dB |
|------|-------------|----------------|--------------|
|------|-------------|----------------|--------------|

|    |       |         |         |
|----|-------|---------|---------|
| 10 | 0.546 | 36.65dB | 48.65dB |
|----|-------|---------|---------|

The result is very close to the value derived with gamma-correction, at 25% signal level. This is good confirmation that the gamma curve is not doing anything unexpected.

#### 4. Noise at high temperature

There was a hint of fixed-pattern noise in the video output at high gain, so the camera was allowed to heat up such that the sensors reached 63°C. A final measurement was then made at +12dB gain. This time, instead of using only the luma (Y) channel, the signal was fully decoded into RGB using ITU-709 a chroma re-sampling filter and decoding equations. This is the same process that I used for decoding the Macbeth Chart image file. For all the other noise measurements, I have used only the luma (Y') channel because the noise was visually fairly neutral when viewed on a Sony 36" HD CRT monitor. However, for investigating such an extreme condition, it is a good idea to see what is happening in the RGB channels as well. The disadvantage is that processing takes a lot longer.

|      | Levels |       |       | Noise  |        |        |
|------|--------|-------|-------|--------|--------|--------|
| File | R      | G     | B     | R      | G      | B      |
| 11   | 0.418  | 0.452 | 0.800 | -33.98 | -35.85 | -25.53 |

There is some visible vertical patterning, but the level is very low. It is most visible in the luma channel, the chroma channels do not seem to have it at all.

It is difficult to see in this sample (495x307 pixels cropped from the centre), but it is rather more visible when the camera is panned across a plain image. Even at this level it might be a problem in some productions. There was no evidence of the pattern at normal temperatures, but it could well be significant on difficult scenes (low video level, plain background, slow pan).

#### 5. Conclusion

Noise levels are lower than was measured in the first tests, by about 7dB. However, the noise is still 9dB short of the specification's claim of 54dB. Based on these tests, this is still the most noisy HDTV camera measured so far. Only the Panasonic HDX400 has similar noise levels, and that camera has been dropped by the BBC. Indeed, it was the visible noise from the HDX900 that started me measuring noise levels in cameras.

For comparison, the HPX500 noise level is consistently about 3dB lower, and the HPX 3000 is about 2dB less noisy. The Varicam is 1dB more noisy, but that camera is “allowed” because of its unique features.

It seems that noise is generated within the digital part of the camera, after gamma-correction, because noise distribution does not follow the slope of the gamma curve; quite possibly, it is the low-level fixed pattern noise that is polluting the head noise and so returning excessive noise levels.
